

# DISCRETE INVARIANTS OF GENERICALLY INCONSISTENT SYSTEMS OF LAURENT POLYNOMIALS

LEONID MONIN

ABSTRACT. Let  $\mathcal{A}_1, \dots, \mathcal{A}_k$  be finite sets in  $\mathbb{Z}^n$  and let  $Y \subset (\mathbb{C}^*)^n$  be an algebraic variety defined by a system of equations

$$f_1 = \dots = f_k = 0,$$

where  $f_1, \dots, f_k$  are Laurent polynomials with supports in  $\mathcal{A}_1, \dots, \mathcal{A}_k$ . Assuming that  $f_1, \dots, f_k$  are sufficiently generic, the Newton polyhedron theory computes discrete invariants of  $Y$  in terms of the Newton polyhedra of  $f_1, \dots, f_k$ . It may appear that the generic system with fixed supports  $\mathcal{A}_1, \dots, \mathcal{A}_k$  is inconsistent. In this paper, we compute discrete invariants of algebraic varieties defined by system of equations which are generic *in the set of consistent system* with support in  $\mathcal{A}_1, \dots, \mathcal{A}_k$  by reducing the question to the Newton polyhedra theory. Unlike the classical situation, not only the Newton polyhedra of  $f_1, \dots, f_k$ , but also the supports  $\mathcal{A}_1, \dots, \mathcal{A}_k$  themselves appear in the answers.

## 1. INTRODUCTION.

With a Laurent polynomial  $f$  in  $n$  variables one can associate its support  $\text{supp}(f) \subset \mathbb{Z}^n$  which is the set of exponents of monomials having non-zero coefficient in  $f$  and its Newton polyhedra  $\Delta(f) \subset \mathbb{R}^n$  which is the convex hull of the support of  $f$  in  $\mathbb{R}^n$ . Consider an algebraic variety  $Y \subset (\mathbb{C}^*)^n$  defined by a system of equations

$$(1) \quad f_1 = \dots = f_k = 0,$$

where  $f_1, \dots, f_k$  are Laurent polynomials with the supports in finite sets  $\mathcal{A}_1, \dots, \mathcal{A}_k \subset \mathbb{Z}^n$ . The Newton polyhedra theory computes invariants of  $Y$  assuming that the system (1) is generic enough. That is, there exists a proper algebraic subset  $\Sigma$  in the space  $\Omega$  of  $k$ -tuples of Laurent polynomials  $f_1, \dots, f_k$  such that the corresponding discrete invariant is constant in  $\Omega \setminus \Sigma$  and could be computed in terms of polyhedra  $\Delta_1, \dots, \Delta_k$ . One of the first examples of such result is the Bernstein-Kouchnirenko theorem (see [B]).

**Theorem 1** (Bernstein-Kouchnirenko). *Let  $f_1, \dots, f_n$  be generic Laurent polynomials with supports in  $\mathcal{A}_1, \dots, \mathcal{A}_n$ . Then all solutions of the system  $f_1 = \dots = f_n = 0$  in  $(\mathbb{C}^*)^n$  are non-degenerate and the number of them is equal to*

$$n! \text{Vol}(\Delta_1, \dots, \Delta_n),$$

where  $\Delta_i$  is the convex hull of  $\mathcal{A}_i$  and  $\text{Vol}$  is the mixed volume.

For some of other examples see [DKh], [Kh], [Kh2]. If  $(f_1, \dots, f_k) \in \Sigma$ , the invariants of  $Y$  depend not only on  $\Delta_1, \dots, \Delta_k$  and, in general, are much harder to compute.

In the case that  $\mathcal{A}_1, \dots, \mathcal{A}_k$  are such that the general system is inconsistent in  $(\mathbb{C}^*)^n$  one can modify the question in the following way. What are discrete invariants of a zero set of

*Key words and phrases.* Newton polyhedra, Laurent polynomials, Generically inconsistent systems, Resultants.

generic consistent system with given supports? The main result of this paper is Theorem 14 which reduces this question to the Newton polyhedra theory. In this situation, the discrete invariants are computed in terms of supports themselves, not the Newton polyhedra. Some examples of applications of Theorem 14 are given in Section 5 (in particular we obtain a generalization of the Bernstein-Kouchnirenko Theorem).

**Acknowledgments.** The author would like to thank Askold Khovanskii for the proposing this problem and for his enthusiasm and support during the work as well as Bernd Schober for very useful comments on the earlier versions of the paper.

## 2. PRELIMINARY FACTS ON THE SET OF CONSISTENCY.

The material of this section is well-known (see for example [GKZ], [St], [D'AS]).

**2.1. Definition of the incidence variety and the set of consistency.** Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  be a collection of  $k$  finite subsets of the lattice  $\mathbb{Z}^n$ . The space  $\Omega_A$  of Laurent polynomials  $f_1, \dots, f_k$  with supports in  $\mathcal{A}_1, \dots, \mathcal{A}_k$  is isomorphic to  $(\mathbb{C})^{|\mathcal{A}_1| + \dots + |\mathcal{A}_k|}$ , where  $|\mathcal{A}_i|$  is the number of points in  $\mathcal{A}_i$ .

*Definition 1.* The *incidence variety*  $\tilde{X}_A \subset (\mathbb{C}^*)^n \times \Omega_A$  is defined as:

$$\tilde{X}_A = \{(p, (f_1, \dots, f_k)) \in (\mathbb{C}^*)^n \times \Omega_A \mid f_1(p) = \dots = f_k(p) = 0\}.$$

Let  $\pi_1 : (\mathbb{C}^*)^n \times \Omega_A \rightarrow (\mathbb{C}^*)^n$ ,  $\pi_2 : (\mathbb{C}^*)^n \times \Omega_A \rightarrow \Omega_A$  be natural projections to the first and the second factors of the product.

*Definition 2.* The *set of consistency*  $X_A \subset \Omega_A$  is the image of  $\tilde{X}_A$  under the projection  $\pi_2$ .

**Theorem 2.** *The incidence variety  $\tilde{X}_A \subset (\mathbb{C}^*)^n \times \Omega_A$  is a smooth algebraic variety.*

*Proof.* Indeed, the projection  $\pi_1$  restricted to  $\tilde{X}_A$ :

$$\pi_1 : \tilde{X}_A \rightarrow (\mathbb{C}^*)^n$$

forms a vector bundle of rank  $|\mathcal{A}_1| + \dots + |\mathcal{A}_k| - k$ . That is because for a point  $p \in (\mathbb{C}^*)^n$  the preimage  $\pi_1^{-1}(p) \subset \tilde{X}_A$  is given by  $k$  independent linear equations on the coefficients of polynomials  $f_1, \dots, f_k$ .  $\square$

We will say that a semi-algebraic subset  $X$  of  $\mathbb{C}^N$  is irreducible if for any two polynomials  $f, g$  such that  $fg|_X = 0$  either  $f|_X = 0$  or  $g|_X = 0$ .

**Corollary 3.** *The set of consistency  $X_A$  is an irreducible semi-algebraic subset of  $\Omega_A$ .*

*Proof.* Since  $X_A = \pi_2(\tilde{X}_A)$  is the image of an irreducible algebraic variety  $\tilde{X}_A$  under the algebraic map  $\pi_2$ , it is semi-algebraic and irreducible.  $\square$

**2.2. Codimension of the set of consistency.** For a collection  $B = (\mathcal{B}_1, \dots, \mathcal{B}_\ell)$  of finite subsets of  $\mathbb{Z}^n$  let  $\mathcal{B} = \mathcal{B}_1 + \dots + \mathcal{B}_\ell$  be the Minkowski sum of all subsets in the collection and let  $L(B)$  be the linear subspace parallel to the minimal affine subspace containing  $\mathcal{B}$ .

*Definition 3.* The defect of a collection  $B = (\mathcal{B}_1, \dots, \mathcal{B}_\ell)$  of finite subsets of  $\mathbb{Z}^n$  is given by

$$\text{def}(\mathcal{B}_1, \dots, \mathcal{B}_\ell) = \dim(L(B)) - \ell.$$

For a subset  $J \subset \{1, \dots, \ell\}$  let us define the collection  $B_J = (\mathcal{B}_i)_{i \in J}$ . For the simplicity we denote the defect  $\text{def}(B_J)$  by  $\text{def}(J)$ , and the linear space  $L(B_J)$  by  $L(J)$ .

The following theorem provides a criterion for a system of Laurent polynomials with supports in  $\mathcal{A}_1, \dots, \mathcal{A}_k$  to be generically consistent.

**Theorem 4** (Bernstein). *A system of generic equations  $f_1 = \dots = f_k = 0$  of Laurent polynomials with supports in  $\mathcal{A}_1, \dots, \mathcal{A}_k$  respectively has a common root if and only if for any  $J \subset \{1, \dots, k\}$  the defect  $\text{def}(J)$  is nonnegative.*

According to the Bernstein theorem, if there exist subcollection of  $A$  with negative defect, the codimension of the set of consistency is positive. We will call such collections  $A$  *generically inconsistent*. The following theorem of Sturmfels determines the precise codimension of  $X_A$ .

**Theorem 5** ([St], Theorem 1.1). *Let  $\mathcal{A}_1, \dots, \mathcal{A}_k$  be such that the generic system with supports in  $\mathcal{A}_1, \dots, \mathcal{A}_k$  is inconsistent. Then the codimension of the set of consistency  $X_A$  in  $\Omega_A$  is equal to the maximum of the numbers  $-\text{def}(J)$ , where  $J$  runs over all subsets of  $\{1, \dots, k\}$ .*

*Definition 4.* For a collection  $\mathcal{A}_1, \dots, \mathcal{A}_k$  of finite subsets of  $\mathbb{Z}^n$  we will denote by  $d(\mathcal{A})$  the smallest defect of a subcollection of  $A$ :

$$d(A) = \min\{\text{def}(J) \mid J \subset \{1, \dots, k\}\}.$$

We will say that a collection  $A$  is generically inconsistent if the minimal defect  $d(A)$  is negative.

*Definition 5.* For a generically inconsistent collection  $A$  we will call a subcollection  $J$  *essential* if  $\text{def}(J) = d(A)$  and  $\text{def}(I) > d(A)$  for any  $I \subset J$ . In other words,  $J$  is the minimal by inclusion subcollection with the smallest defect.

This definition is related to the definition of an essential subcollection given in [St], but is different in general. Sturmfels was interested in resultants, so his definition was adapted to the case  $d(A) = -1$  in which both definitions coincide.

The essential subcollection is unique. For  $d = -1$  this was shown in [St] (Corollary 1.1), in Lemma 8 we prove this statement for arbitrary  $d < 0$ . In the case  $d(A) = 0$  we will call define the empty subcollection to be the unique essential subcollection.

*Remark 1.* In the case  $d(A) = 0$  the subcollections  $J$  such that  $\text{def}(J) = 0$  and  $\text{def}(I) > 0$  for any nonempty  $I \subset J$  are also playing important role (see [Kh2]).

### 3. THE DEFECT AND ESSENTIAL SUBCOLLECTIONS.

**3.1. Uniqueness of essential subcollection.** Let  $\mathcal{A}_1, \dots, \mathcal{A}_k$  be finite subsets of the lattice  $\mathbb{Z}^n$ . As before, for any  $J \subset \{1, \dots, k\}$ , let  $L(J)$  be the vector subspace parallel to the minimal affine subspace containing the Minkowski sum  $\mathcal{A}_J = \sum_{i \in J} \mathcal{A}_i$  with  $i \in J$ .

Most of the results of this section are based on the obvious observation that the dimension of vector subspaces of  $\mathbb{R}^n$  is subadditive with respect to sums. That is for two vector subspaces  $V, W \subset \mathbb{R}^n$  the following holds:

$$\dim(V + W) = \dim(V) + \dim(W) - \dim(V \cap W) \leq \dim(V) + \dim(W).$$

The immediate corollary of the relation above is the subadditivity of defect with respect to disjoint unions. More precisely, for disjoint  $I, J \subset \{1, \dots, k\}$  the following is true:

$$(2) \quad \text{def}(I \cup J) = \text{def}(I) + \text{def}(J) - \dim(L(I) \cap L(J)) \leq \text{def}(I) + \text{def}(J).$$

**Lemma 6.** *Let  $K = I \cap J$ , then  $\text{def}(I \cup J) \leq \text{def}(I) + \text{def}(J) - \text{def}(K)$ .*

*Proof.* By the definition of the defect we have:

$$\text{def}(I \cup J) = \dim(L(I \cup J)) - \#(I \cup J) = \dim(L(I \cup J)) - \#I - \#J + \#K,$$

where  $\#I, \#J, \#K$  are the sizes of  $I, J, K$  respectively. But also

$$\text{def}(I) + \text{def}(J) - \text{def}(K) = \dim(L(I)) + \dim(L(J)) - \dim(L(K)) - \#I - \#J + \#K,$$

so we need to compare  $\dim(L(I \cup J))$  and  $\dim(L(I)) + \dim(L(J)) - \dim(L(K))$ . For this notice that

$$\dim(L(I \cup J)) = \dim(L(I)) + \dim(L(J)) - \dim(L(I) \cap L(J)),$$

and since  $K \subset I \cap J$ , the space  $L(K)$  is a subspace of  $L(I) \cap L(J)$ , so

$$\dim(L(I \cup J)) \leq \dim(L(I)) + \dim(L(J)) - \dim(L(K)),$$

which finishes the proof.  $\square$

**Corollary 7.** *Let  $J$  and  $I$  be two not equal minimal by inclusion subcollections with minimal defect. Then  $I \cap J = \emptyset$ .*

*Proof.* Indeed, let  $I \cap J = K \neq \emptyset$ . Since  $K \subset J$  and  $K \neq J$ , the defect of  $K$  is larger than the defect of  $J$ , so  $\text{def}(J) - \text{def}(K) < 0$ . But by Lemma 1

$$\text{def}(I \cup J) \leq \text{def}(I) + \text{def}(J) - \text{def}(K) < \text{def}(I) = \text{def}(J),$$

which contradicts  $\text{def}(I) = \text{def}(J) = d(A)$ .  $\square$

**Lemma 8.** *Let  $A$  be a collection of finite subsets of  $\mathbb{Z}^n$  with  $d(A) \leq 0$ , then the minimal by inclusion subcollection with minimal defect exists and is unique.*

*Proof.* In the case  $d(A) = 0$  the unique essential subcollection is the empty collection  $J = \emptyset$ .

For  $d(A) < 0$ , existence is clear. For uniqueness, assume that  $I$  and  $J$  are two different minimal by inclusion subcollections with minimal defect, then by Lemma 1  $I \cap J = \emptyset$ . But for disjoint subcollections  $I, J$  by relation (2) we have:

$$\text{def}(I \cup J) \leq \text{def}(I) + \text{def}(J) < \text{def}(I) = \text{def}(J),$$

since  $\text{def}(I) = \text{def}(J) = d(A) < 0$ . But this contradicts the minimality of  $I$  and  $J$ .  $\square$

**3.2. Some properties of the essential subcollection.** Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  be a collection of finite subsets of the lattice  $\mathbb{Z}^n$ . For the subcollection  $J$  denote by  $J^c = \{1, \dots, k\} \setminus J$  the compliment subcollection and by  $\pi_J : \mathbb{R}^n \rightarrow \mathbb{R}^n / L(J)$  the natural projection.

**Lemma 9.** *In the notations above let  $\pi_J(J^c)$  be the collection  $(\pi_J(\mathcal{A}_i))_{i \in J^c}$ . Then the following relations hold:*

1.  $\text{def}(A) = \text{def}(J) + \text{def}(\pi_J(J^c))$ ,
2.  $d(A) \geq d(J) + d(\pi_J(J^c))$ ,
3. if  $J$  furthermore is the unique essential subcollection of  $A$ , then  $d(\pi_J(J^c)) = 0$ .

*Proof.* The proof of the part 1. is a direct calculation:

$$\begin{aligned} \text{def}(J \cup J^c) &= \dim(L(J \cup J^c)) - \#(J \cup J^c) = \\ &= \dim(L(J)) + \dim L(\pi_J(J^c)) - \#(J) - \#(J^c) = \text{def}(J) + \text{def}(\pi_J(J^c)). \end{aligned}$$

For the part 2. note, that for any  $B \subset J$ ,  $C \subset J^c$  one has  $L(B) \subset L(J)$  and hence the following is true:

$$\text{def}(\pi_B(C)) \geq \text{def}(\pi_J(C)).$$

This implies that:

$$\text{def}(B \cup C) = \text{def}(B) + \text{def}(\pi_B(C)) \geq \text{def}(B) + \text{def}(\pi_J(C)) \geq d(J) + d(\pi_J(J^c)).$$

For the part 3. assume that  $\text{def}(\pi_J(I)) < 0$  for some  $I \subset J^c$ . Then by part 1. we have

$$\text{def}(J \cup I) = \text{def}(J) + \text{def}(\pi_J(I)) < \text{def}(J).$$

Since the defect of empty collection is 0, the minimal defect  $d(\pi_J(I))$  is also 0.  $\square$

**Proposition 10.** *Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  be a collection of finite subsets of  $\mathbb{Z}^n$  such that  $\text{def}(A) = d(A) < 0$ . Let  $J$  be the unique essential subcollection of the collection  $A$ . Then for any  $i \in J$ , the following is true:*

$$\text{def}(A \setminus \{i\}) = d(A \setminus \{i\}) = d(A) + 1.$$

*Proof.* For a collection  $B$  and an element  $b \in B$  the defect can not increase by more than 1 after removing  $b$ :

$$\text{def}(B \setminus \{b\}) \leq \text{def}(B) + 1,$$

where the equality holds if and only if  $L(B \setminus \{b\}) = L(B)$ . For the essential subcollection  $J$  and any  $i \in J$ , the defect  $\text{def}(J \setminus \{i\})$  is strictly greater than  $\text{def}(J)$ , so it is equal to  $\text{def}(J) + 1 = \text{def}(A) + 1$ . Hence,  $L(J) = L(J \setminus \{i\})$ , and in particular  $\pi_J = \pi_{J \setminus \{i\}}$ .

Since  $\text{def}(A) = d(A) = \text{def}(J)$ , the defect  $\text{def}(\pi_J J^c)$  is equal to zero by part 1. of Lemma 9. Moreover, one has:

$$\text{def}(A \setminus \{i\}) = \text{def}(J \setminus \{i\}) + \text{def}(\pi_{J \setminus \{i\}} J^c) = \text{def}(J \setminus \{i\}) + \text{def}(\pi_J J^c) = \text{def}(A) + 1.$$

By part 2. and part 3. of Lemma 9 one has:

$$d(A \setminus \{i\}) \geq d(J \setminus \{i\}) + d(\pi_{J \setminus \{i\}} J^c) = d(J \setminus \{i\}) + d(\pi_J J^c) = d(J) + 1.$$

But since  $\text{def}(A \setminus \{i\}) = \text{def}(A) + 1$ , the minimal defect  $d(A \setminus \{i\})$  is also equal to  $\text{def}(A) + 1$ .  $\square$

**Corollary 11.** *Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_{n+d})$  be a collection of finite subsets of  $\mathbb{Z}^n$  such that  $A$  is an essential collection of defect  $-d$ , i.e.*

$$-d = d(A) = \text{def}(A) < \text{def}(J),$$

*for any proper  $J \subset \{1, \dots, n+d\}$ . Then there exists a subcollection  $I$  of size  $\dim(L(A)) = n$  with  $d(I) = 0$ .*

*Proof.* Apply Proposition 10 successively.  $\square$

#### 4. THE MAIN THEOREM.

In this section we will prove the main theorem. For a collection  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  of finite subsets of  $\mathbb{Z}^n$  and subcollection  $J$  let  $\mathcal{A}_J, L(J)$ , and  $\pi_J$  be as before. Furthermore, denote by

- $\Lambda(J) = L(J) \cap \mathbb{Z}^n$  the lattice of integral points in  $L(J)$ ;
- $G(J)$  the group generated by all the differences of the form  $(a - b)$  with  $a, b \in \mathcal{A}_i$  for any  $i \in J$ ;
- $\text{ind}(J)$  the index of  $G(J)$  in  $\Lambda(J)$ ;

**4.1. Zero set of the generic essential system.** In this subsection we will work with the systems of Laurent polynomials  $f_1 = \dots = f_k = 0$  with supports in  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  such that the essential subcollection is  $A$  itself. We call such systems essential.

**Theorem 12.** *Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_{n+d})$  be a collection of finite subsets of  $\mathbb{Z}^n$  such that  $\text{ind}(A) = 1$ . Let also  $A$  be an essential collection, i.e.*

$$d = d(A) = \text{def}(A) < \text{def}(J),$$

*for any proper  $J \subset \{1, \dots, n+d\}$ . Then for a generic consistent system  $\mathbf{f} = (f_1, \dots, f_k) \in X_A \subset \Omega_A$ , the corresponding zero set  $Y_{\mathbf{f}}$  is a single point.*

Here, and everywhere in this paper, by a generic point in the algebraic variety  $X$  parametrizing systems of Laurent polynomials we mean a point in  $X \setminus \Sigma$  for the fixed subvariety  $\Sigma$  of smaller dimension.

*Proof.* By Proposition 11 there exists a subcollection  $I$  of  $A$  of size  $n$  with  $d(I) = 0$ . Without loss of generality let us assume that  $I = \{1, \dots, n\}$ . The space  $\Omega_A$  of polynomials with supports in  $A$  could be thought as a product

$$\Omega_A = \Omega_I \times \Omega_{I^c},$$

where  $\Omega_I$  and  $\Omega_{I^c}$  are the spaces of systems of Laurent polynomials with supports in  $I$  and  $I^c$  respectively. Let  $p : \Omega_A \rightarrow \Omega_I$  be the natural projection on the first factor.

By the Bernstein criterion the subsystem  $f_1 = \dots = f_n = 0$  is generically consistent. Moreover, the Bernstein-Kouchnirenko Theorem asserts that the generic number of solutions in  $(\mathbb{C}^*)^n$  is  $n! \text{Vol}(\Delta_1, \dots, \Delta_n)$ , where  $\Delta_i$  is the convex hull of  $\mathcal{A}_i$ , and in particular is finite. Let us denote by  $\Omega_I^{\text{gen}} \subset \Omega_I$  the Zariski open subset of systems  $f_1 = \dots = f_n = 0$  with exactly  $n! \text{Vol}(\Delta_1, \dots, \Delta_n)$  roots.

For each point  $\mathbf{f}_I \in \Omega_I^{\text{gen}}$  the preimage  $p^{-1}(\mathbf{f}_I)$  of the projection  $p$  restricted to the set of consistency  $X_A$  is a union of  $n! \text{Vol}(\Delta_1, \dots, \Delta_n)$  vector spaces  $V_j(\mathbf{f}_I)$ 's of dimension  $|\mathcal{A}_{n+1}| + \dots + |\mathcal{A}_{n+d}| - d$  each. Since  $G(A) = \mathbb{Z}^n$  the intersection of any two of these vector spaces has smaller dimension for generic  $\mathbf{f}_I \in \Omega_I^{\text{gen}}$ . Denote by  $X'_A \subset X_A$  the set of points which belongs to exactly one of the  $V_j(\mathbf{f}_I)$ 's.

By construction, the dimension of  $X'_A$  is equal to  $|\mathcal{A}_1| + \dots + |\mathcal{A}_{n+d}| - d = \dim(X_A)$ . Since  $X_A$  is irreducible, the complement  $\Sigma = X_A \setminus X'_A$  is an algebraic subvariety of smaller dimension. But for any  $\mathbf{f} \in X'_A$  the zero set  $Y_{\mathbf{f}}$  is a single point, so the theorem is proved.  $\square$

**Corollary 13.** *Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  be an essential collection of finite subsets of  $\mathbb{Z}^n$  of defect  $d(A) = \text{def}(A) = d$ . Then for the generic  $\mathbf{f} \in X_A \subset \Omega_A$  the zero set  $Y_{\mathbf{f}}$  is a finite disjoint union of  $\text{ind}(A)$  subtori of dimension  $n - k + d$  which are different by a multiplication by elements of  $(\mathbb{C}^*)^n$ .*

*Proof.* The lattice  $G(A)$  generated by all of the differences in  $\mathcal{A}_i$ 's defines a torus  $T \simeq (\mathbb{C}^*)^{k-d}$  for which  $G(A)$  is the lattice of characters. The inclusion  $G(A) \hookrightarrow \mathbb{Z}^n$  defines the homomorphism:

$$p : (\mathbb{C}^*)^n \rightarrow T.$$

The kernel of the homomorphism  $p$  is the subgroup of  $(\mathbb{C}^*)^n$  consisting of finite disjoint union of  $\text{ind}(A)$  subtori of dimension  $n - k + d$  which are different by a multiplication by elements of  $(\mathbb{C}^*)^n$ .

The multiplication of Laurent polynomials by monomials does not change the zero set of a system. For any  $i$  let  $\tilde{\mathcal{A}}_i$  be any translation of  $\mathcal{A}_i$  belonging to  $G(J)$ . We can think of  $\tilde{\mathcal{A}}_i$

as support of a Laurent polynomial on  $T$ . We will denote by  $\tilde{A}$  the collection  $(\tilde{A}_1, \dots, \tilde{A}_k)$  understood as a collection of supports of Laurent polynomials on the torus  $T$ . The collection  $\tilde{A}$  satisfies the assumptions of Theorem 12.

With a system  $\mathbf{f} \in \Omega_A$  one can associate a system of Laurent polynomials  $\tilde{\mathbf{f}}$  on  $T$  in a way described above. The zero set of  $Y_{\mathbf{f}}$  of a system  $\mathbf{f}$  is given by

$$Y_{\mathbf{f}} = p^{-1}(Y_{\tilde{\mathbf{f}}}) \text{ (in particular } Y_{\mathbf{f}} \simeq Y_{\tilde{\mathbf{f}}} \times \ker(p)),$$

where  $Y_{\tilde{\mathbf{f}}}$  is the zero set of a system  $\tilde{\mathbf{f}}$  on  $T$ . By Theorem 12 for the generic system  $\tilde{\mathbf{f}} \in X_{\tilde{A}} \subset \Omega_{\tilde{A}}$  the zero set  $Y_{\tilde{\mathbf{f}}}$  which finishes the proof.  $\square$

#### 4.2. General systems.

**Theorem 14.** *Let  $A = (\mathcal{A}_1, \dots, \mathcal{A}_k)$  be a collection of finite subsets of  $\mathbb{Z}^n$  with the essential subcollection  $J$ . Then for the generic system  $\mathbf{f} \in X_A \subset \Omega_A$  the zero set  $Y_{\mathbf{f}}$  is a disjoint union of  $\text{ind}(J)$  varieties  $Y_1, \dots, Y_{\text{ind}(J)}$  each of which is given by a  $\Delta$  non-degenerate system with the same Newton polyhedra.*

Theorem 14 provides a solution for the problem of computing discrete invariants of the generic solution of the discrete invariants of generically inconsistent systems by reducing it to the classical Newton polyhedra theory. The concrete examples of applications of Theorem 14 are given in the next section.

*Proof.* Without loss of generality let us assume that  $J = \{1, \dots, l\}$ . By Corollary 13 there exists a Zariski open subset  $X'_A \subset X_A$ , such that for any  $\mathbf{f} = (f_1, \dots, f_k) \in X'_A$  the zero set of the system  $f_1 = \dots = f_l = 0$  is a finite disjoint union of  $\text{ind}(J)$  subtori  $V_1, \dots, V_{\text{ind}(J)}$  which are different by a multiplication by an element of  $(\mathbb{C}^*)^n$ .

For the generic point  $\mathbf{f} = (f_1, \dots, f_k) \in X'_A$  the restrictions of Laurent polynomials  $f_{l+1}, \dots, f_k$  to each  $V_i$  are non-degenerate Laurent polynomials with Newton polyhedra  $\pi_J(\Delta_{l+1}), \dots, \pi_J(\Delta_{l+1})$ , respectively.  $\square$

**Corollary 15.** *For the generic system  $\mathbf{f} \in X_A \subset \Omega_A$  the zero set  $Y_{\mathbf{f}}$  is a non-degenerate complete intersection. That is  $Y_{\mathbf{f}}$  is defined by  $\text{codim}(Y_{\mathbf{f}})$  equations with independent differentials.*

*Proof.* Indeed, each of the components  $Y_i \subset V_i$  of  $Y_{\mathbf{f}}$  is defined by the restrictions of Laurent polynomials  $f_{l+1}, \dots, f_k$  to  $V_i$ , and hence is a non-degenerate complete intersection in  $V_i$  for generic consistent system  $\mathbf{f}$ .

But the union of moved subtori  $V_1, \dots, V_{\text{ind}(J)}$  could be defined by the  $\text{codim}(V_i)$  more independent equations in  $(\mathbb{C}^*)^n$ , which finishes the proof.  $\square$

### 5. DISCRETE INVARIANTS

Theorem 14 asserts that any discrete invariant which can be computed by means of the theory of Newton polyhedra could be also computed for the zero set  $Y_{\mathbf{f}}$  of generic consistent system with generically inconsistent supports. In this section we will give two examples of such calculations, but absolutely the same strategy is applicable to other discrete invariants such as Hodge–Deligne numbers, or the number of connected components (which were computed in the classical case in [DKh] and [Kh2] respectively).

Through all of this section by the volume on the vector space  $V$  with the lattice  $\Lambda$  inside we mean the translation invariant volume normalized by the following condition: for any  $v_1, \dots, v_k$  the generators of the lattice  $G$ , the volume the parallelepiped with sides  $v_1, \dots, v_k$  is equal to 1.

**Theorem 16** (Number of roots). *Let  $\mathcal{A}_1, \dots, \mathcal{A}_{n+k} \subset \mathbb{Z}^n$  be such that  $d(\mathcal{A}) = -k$  and  $J$  be the unique essential subcollection. Then the zero set  $Y_{\mathbf{f}}$  of the generic consistent system has dimension 0, and the number of points in  $Y_{\mathbf{f}}$  is equal to*

$$(n - \#J + k)! \cdot \text{ind}(J) \cdot \text{Vol}(\pi_J(\Delta_i)_{i \notin J}),$$

where  $\Delta_i$  is the convex hull of  $\mathcal{A}_i$  and  $\text{Vol}$  is the mixed volume on  $\mathbb{R}^n/L(J)$  normalized with respect to the lattice  $\mathbb{Z}^n/\Lambda(J)$ .

If  $k = 0$  this theorem coincides with the Bernstein-Kouchnirenko theorem. In the case  $k = 1$  the generic number of solution appears as the corresponding degree of  $A$ -resultant and was computed in [D'AS].

*Proof.* First note that for generic  $\mathbf{f} \in X_{\mathcal{A}}$  the dimension  $\dim(Y_{\mathbf{f}})$  is equal to  $\dim(\tilde{X}_{\mathcal{A}}) - \dim(X_{\mathcal{A}}) = 0$ . By Theorem 14 the generic zero set  $Y_{\mathbf{f}}$  is a disjoint union of  $\text{ind}(J)$  varieties  $Y_1, \dots, Y_{\text{ind}(J)}$  each of which is defined by generic system with Newton polyhedra  $\pi_J(\Delta_i)$  for  $i \notin J$ . By the Bernstein-Kouchnirenko formula the number of points in  $Y_i$  is finite and is equal to  $(n - \#J + k)! \text{Vol}(\pi_J(\Delta_i)_{i \notin J})$ . Therefore, the number of points in  $Y_{\mathbf{f}}$  is

$$|Y_{\mathbf{f}}| = \sum_{i=1}^{\text{ind}(J)} |Y_i| = (n - \#J + k)! \cdot \text{ind}(J) \cdot \text{Vol}(\pi_J(\Delta_i)_{i \notin J}).$$

□

For simplicity, we will formulate next theorem in the “hypersurface” case, i.e. when the essential subcollection contains all but one supports (the general case could be deduced similarly).

**Theorem 17.** *Let  $\mathcal{A}_1, \dots, \mathcal{A}_k \subset \mathbb{Z}^n$  be such that  $d(\mathcal{A}) < 0$  and let  $J = \{2, \dots, k\}$  be the unique essential subcollection. Then the Euler characteristic and the geometric genus of the zero set  $Y_{\mathbf{f}}$  of the generic consistent system is given by*

$$\begin{aligned} \chi(Y_{\mathbf{f}}) &= (-1)^{n-\dim(J)-1} (n - \dim(J))! \cdot \text{ind}(J) \text{Vol}(\pi_J(\Delta_1)), \\ g(Y_{\mathbf{f}}) &= \text{ind}(J) (B^+(\pi_J(\Delta_1))), \end{aligned}$$

where  $\Delta_1$  is the convex hull of  $\mathcal{A}_1$ ,  $\text{Vol}$  is the volume on  $\mathbb{R}^n/L(J)$  normalized with respect to the lattice  $\mathbb{Z}^n/\Lambda(J)$ , and  $B^+(\Delta)$  is the number of integral point in the interior of  $\Delta$ .

*Proof.* Indeed, by Theorem 14 the generic zero set  $Y_{\mathbf{f}}$  is a disjoint union of  $\text{ind}(J)$  varieties  $Y_1, \dots, Y_{\text{ind}(J)}$  each of which is defined by a generic equation with a Newton polyhedra  $\pi_J(\Delta_1)$ . Therefore, the Euler characteristic of  $Y_i$  is given by  $\chi(Y_i) = (-1)^{n-\dim(J)-1} (n - \dim(J))! \cdot \text{Vol}(\pi_J(\Delta_1))$  (see [Kh1]), and the geometric genus of  $Y_i$  is given by  $g(Y_i) = B^+(\pi_J(\Delta_1))$  (see [Kh]). The theorem follows from the additivity of the Euler characteristic and the geometric genus. □
